These data, indicating that <i>U. indica</i> possesses the bronchodilator activity possibly mediated through a combination of anticholinergic and Ca^{2+} antagonist mechanisms together with selective positive inotropic effect, provide rational for medicinal applications of <i>U. indica</i> in airways and cardiac disorders.

Introduction

Urginea indica Kunth., belonging to the family liliaceae, is a perennial glabrous herb commonly known as "Indian squill" and locally in Pakistan as "Junglipiyaz", where it grows in Salt Range, Kotli Near Mirpur and Mt.Tilla (Baquar, 1989). In the indigenous traditional system of medicine, U. indica is reputed for a number of therapeutic benefits, for which bulb or rhizome are the most commonly employed plant parts. It is chiefly used in chronic bronchitis and asthma. The other actions attributed to U. indica are anthelmintic, cardiotonic in heart insufficiency, deobstruent, digestive, expectorant, stomachic, diuretic, emmenagogue and purgative, in addition to its use in calculous and paralytic affections, rheumatism, leprosy, skin diseases, internal pain and scabies (Baquar, 1989; Kirtikar and Basu, 1987; Prajapati et al., 2003). Bulbs crushed or sliced are also applied under the sole of feet to prevent

burning sensation (Kapoor, 1990; Usmanghani et al., 1997) and are externally used for removing corns and warts (Kapoor, 1990; Prajapati et al., 2003).

Among phytochemical constituents, the glycosides, scillarin-A and scillarin-B have been reported to be present in fresh squill (Prajapati et al., 2003). Other constituents found in squill include flavonoids, carbohydrates, antifungal glycoproteins, steroids, alkaloids, tannins, coumarins and saponins (Abbas et al., 2012; Kameshwari et al., 2012).

Pharmacological evaluations have revealed the presence of antibacterial, antifungal (Shenoy et al., 2006), laxative and spasmodic (Abbas et al., 2012), antioxidant, antiangiogenic and pro-apoptotic activities in U. indica (Deepak and Salimath, 2006).

Despite of its extensive medicinal application in airways hyperactivity disorders and also in cardiac disor-

ders, *U. indica* has not been studied widely to evaluate these medicinal uses. This study was aimed to provide pharmacological basis for the medicinal use of *U. indica* in broncho-spastic disorders like asthma and as cardiac stimulant.

Material and Methods

Plant material and preparation of crude extract

The bulbs of U. indica were collected fresh from fields of Mianwali subsequent to the identification of the plant by an expert taxonomist at the Institute of Pure & Applied Biology, Bahauddin Zakariya University, Multan, Pakistan. A specimen of the plant has been deposited at herbarium of the same institute (voucher no. P. Fl 59-1843). The plant material was washed for any contaminants and subjected to shade drying. The dried plant material (400 g) was ground into coarse powders through electrically driven device and the powder was soaked in 70% aqueous-methanol (v/v) for three days in amber colored glass bottles with occasional shaking. The soaked material was passed through double layered muslin cloth to remove vegetative debris and the obtained fluid was subsequently filtered through filter paper (Williamson et al., 1998). The residue was re -soaked for next three days and the procedure repeated twice. The filtrates were evaporated on a rotary evaporator (R-210, BUCHI, Switzerland) under reduced pressure (-760 mmHg) at 37°C to a thick, semi-solid paste of dark brown colour, the crude extract of U. indica bulb yielding 10%. U. indica extract was solubilized in distilled water for all in vitro experiments.

Animals

Animals used in the study were rabbits of local breed and either sex; housed at the Animal House of the Aga Khan University, Karachi, maintained at 23-25°C. Animals were provided with standard diet and tap water *ad libitum*. Experiments were performed in compliance with the rulings of the Institute of Laboratory Animals Resources, Commission on Life Sciences, National Research Council (NRC, 2011).

Chemicals

Acetylcholine chloride (ACh), carbachol (CCh) and dicylclomine were purchased from Sigma Chemical Co., USA. Chemicals used for preparing physiological salt solutions were ethylenediamine tetra-acetic acid (EDTA), potassium chloride (Sigma Chemical Co.), calcium chloride, glucose, magnesium chloride, magnesium sulfate, potassium dihydrogen phosphate, sodium dihydrogen phosphate, sodium chloride and sodium bicarbonate (Merck, Darmstadt, Germany). All chemical used were of the analytical grade available. Stock solutions of all the chemicals were made in distilled water and their dilutions were made fresh on the day of experiment. The vehicle used for solubilization of drugs had no effect on tissue contractility in the control experiments.

Isolated tissue experiments

Isolated tissue experiments were performed following the methods previously employed in our laboratory (Gilani et al., 1997; 2007).

Trachea was dissected out and kept in Kreb's solution. The trachea was cleaned free from the surrounding fatty tissues and cut into rings having 2-3 mm width (containing 2 cartilages). Each ring was then opened by longitudinal cut on the side opposite to the smooth muscle layer in such a way that smooth muscles were in between the C-shaped cartilaginous part. The isolated preparations were then mounted in tissue baths containing Kreb's solution and aerated with carbogen at 37°C. The composition of Kreb's solution was (mM): NaCl 118.2, NaHCO3 25.0, CaCl2 2.5, KCl 4.7, KH2PO4 1.3, MgSO₄ 1.2 and glucose 11.7 (pH 7.4). A tension of 1 g was applied to the tracheal strips continuously and equilibrated for 1 hour before the addition of any chemical substance. CCh (1 µM) was used to stabilize the preparations until constant responses to successive treatments were achieved (usually after 3-4 exposures). The bronchodilator activity of the plant extract and control drugs was studied on CCh (1 µM) or high K+induced sustained contractions, by adding them in a cumulative manner. Cumulative curves to CCh were constructed using increasing concentration of agonist. When a 3-fold increase in concentration produced no further increment in response, the tissue was washed to re-establish the base-line tension. The CCh CRCs were repeated in the presence of increasing concentrations of U. indica and dicyclomine. Isometric responses were recorded by force transducer (model FORT100) coupled to a Transbridge (model TBM4M, World Precision Instruments, Hertfordshire, UK) and PowerLab data acquisition system (model ML845, AD Instruments, Australia) and computer running Chart software (version 6).

Paired atria from healthy guinea-pigs were dissected out, cleaned of fatty tissues and mounted in 15 mL tissue organ baths containing Kreb's solution, at 32°C and the tissues were aerated with carbogen. The tissues exhibited spontaneous beating under the resting tension of 1 g due to the presence of pacemaker cells. An equilibrium period of 30 min was provided before the application of any chemical substance. Control responses of ACh (0.3μ M) and isoprenaline (1 μ M) were obtained at least in duplicate. Tension changes in the tissue were obtained via a Grass force-displacement transducer (model FT-03) and were recorded using Grass Model 7 Polygraph.

Statistical analysis

All the data expressed are mean \pm standard error of mean (SEM., n = number of experiments) and the median effective concentration (EC₅₀) with 95% agai confidence intervals (CI) concentration–response curves (CRCs) were analyzed by non-linear regression using

confidence intervals (CI) concentration-response curves (CRCs) were analyzed by non-linear regression using GraphPad program (GraphPAD, SanDiego, CA, USA). The statistical parameter applied is the Student's t-test. p<0.05 was considered significantly different.

Results

U. indica caused relaxation of tracheal preparations precontracted with CCh (1 μ M) and K⁺(80 mM) with respective EC₅₀ values of 0.1 mg/mL (0.1-0.2, n = 6) and 0.8 mg/mL (0.5-1.2, n = 6; Figure 1A). Dicyclomine similarly was found to be more potent in inhibiting CCh (1 μ M) induced contractions compared to that against high K⁺ with respective EC₅₀ values of 0.2 μ M (0.1-0.2, n = 5) and 1.8 (1.2-2.5, n = 5; Figure 1B).

When studied for its possible anticholinergic action, *U. indica* produced rightward parallel displacement of the CCh CRCs without suppression of the maximum contractile response at 0.03 mg/mL, followed by non-parallel shift with suppression of the maximum effect at next higher concentration (0.1 mg/mL; Figure 2A). Dicyclomine (0.03 and 0.1 μ M) exhibited a similar pattern of shift in CCh CRCs (Figure 2B).

When studied for its effect on Ca^{2+} influx, *U. indica* shifted $Ca^{2+}CRCs$ towards right in a concentration-

dependent manner (0.1-1 mg/mL), similar to dicyclomine (0.3-3 μ M; Figure 3A and B).

U. indica caused a concentration-dependent (0.01-1.0 mg/mL) increase in the force of spontaneous contractions of paired atria followed by inhibition at the higher concentrations (3.0-10.0 mg/mL) without significantly affecting the rate of contractions (Figure 4).

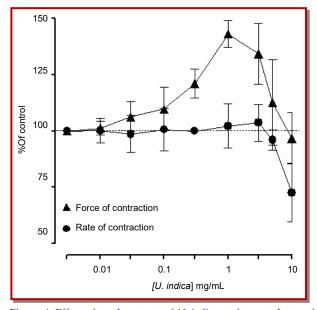

Figure 4: Effect of crude extract of *U. indica* on force and rate of contraction in isolated guinea pig atria. Values are shown as mean \pm SEM, n = 3.

Discussion

U. indica plant has traditionally been used to relieve airways disorders including asthma and bronchitis, therefore, the current study was undertaken to see primarily its bronchodilator effect to rationalize the medicinal uses.

The proposed broncho-relaxant activity of *U. indica* was investigated on CCh (1 μ M) and high K⁺-induced contractions in isolated rabbit tracheal preparations. *U. indica* exhibited relaxant effect on both the contractions with higher potency against CCh-induced contraction, in a manner similar to dicyclomine, a dual blocker of muscarinic receptors and Ca²⁺ influx (Downie et al., 1977; McGrath et al., 1964).

To confirm the antimuscarinic activity, effect of the plant extract was studied on CCh-concentration-response curves constructed in the isolated rabbit tracheal preparations. At lower concentration, U. indica caused rightward displacement of the curve without suppression of the maximum response and at higher concentrations, it shifted the curve in a non-parallel manner with suppression of the maximum response. The parallel shift of CCh-curves at lower concentration of *U*. indica without suppression of maximum response is indication for blockade of muscarinic receptors in a competitive manner; whereas, non-parallel shift of CCh -curves observed at higher concentration of U. indica with suppression of the maximum response can be attributed to the presence of some non-competitive inhibitor like that exhibited by a Ca²⁺-channel blocker. The CCB effect was confirmed when pretreatment of

the tissue with *U. indica* also produced a concentrationdependent rightward shift in the Ca²⁺ concentrationresponse curve, similar to dicyclomine.

The Ca²⁺ channel blockers have been found to be useful in broncho-spastic disorders (Ahmed, 1992; Mathewson, 1985) and muscarinic antagonists are also included as present day treatment for the relief from asthma and similar diseases (Boushey, 2006). The tone of bronchiolar smooth muscles is regulated by the parasympathetic division of autonomic nervous system and reflex increase in parasympathetic activity may contribute toward bronchoconstriction because the respiratory tract is rich in cholinergic innervations through vagal fibers linked to M₁ muscarinic receptors situated in the mucosal surface of the respiratory tract. The mucus secretions are also involved in adding up miseries to the pathology of the respiratory tract particularly submucosal glands are rich in parasympathetic innervetions mostly through M₃ receptors and this may be one of the plausible explanations using muscarinic antagonist in chronic obstructive pulmonary disease as well as asthma (Barnes and Hansel, 2004).

In isolated guinea-pig atria, U. indica produced positive inotropic effect at lower concentrations followed by inhibition of the contractile force at higher concentrations, suggesting the presence of dose-related cardiotonic effect in U. indica. Indian squill is already been used in its crude form for the treatment of cardiac insufficiency but there is not report on cardiac stimulant effect of the plant itself, however the plant is reported to contain scillaren-A and scillaren-B (Prajapati et al., 2003), the cardio-active glycosides producing their effect through inhibition of Na+/K+-ATPase, similar to that of digitalis glycosides (Barceloux, 2008). Cardiac inhibitory effect observed at higher concentrations could possibly be the result of the presence of Ca2+ channel blocking activity in U. indica. These results, showing cardiac stimulant effect in U. indica, explain this use of the plant in traditional medicine for cardiac insufficiency.

These investigations indicate that the crude extract of *U. indica* possesses bronchodilator activity possibly mediated through a dual blockade of Ca²⁺ influx and muscarininc receptors and cardiac stimulant effect through selective inotropic effect, which can be the possible reason for its medicinal use in airways disorders and cardiac insufficiency.
